## Summary

- In 2014, the annual average out-of-pocket expenditure across all households for outpatient care was more than double that of inpatient care (Rs. 7276 *vis-a-vis* Rs. 3204). If one considers only affected households (i.e. households with at least one episode of hospitalization or outpatient visit), the average annual expenditure was not very different for inpatient and outpatient care. This is because the frequency of inpatient care is significantly lower than outpatient care. Similarly, due to low frequency of occurrence of childbirth as inpatient case, the annual average expenditure across all households is only about Rs. 523, while that of affected households (household with at least one case of childbirth as inpatient) was Rs. 8511.
- The use of public hospitals is relatively high for inpatient care than outpatient care, particularly among the poorer sections of the population. This possibly arises from the fact that the average expense for inpatient care in a private facility is about 3-4 times higher than a public facility, while for outpatient care, the difference is relatively small. Interestingly, unlike inpatient and outpatient cases, public facilities provided much of the care for childbirth as inpatient cases, particularly in rural areas.
- The relatively low rate of hospitalization among the poor population and their high dependence on public facilities for inpatient care is possibly an indication of the fact that financial support extended by the government in the form of health insurance schemes to the poorer sections of the population has been inadequate. On average, only about a fifth of the inpatient affected households had some insurance coverage. Of these, more than 80 per cent were covered by government supported health insurance schemes.
- The difference in the average hospitalization expenditure of households covered by government health insurance schemes *vis-à-vis* those households which are not covered by any insurance scheme was more for richer households in urban areas than poorer households in rural areas. This is possibly because most of the government employees

covered under CGHS and ESIS are located in urban areas and belong to relatively richer quintiles. On the other hand, households covered by GFHIS in rural areas and among the poorer quintiles, are supported by cashless insurance schemes of the government and their ability to incur inpatient expenditure in the absence of insurance support is relatively limited.

- Expenditure per episode was highest for the treatment of cancer for both inpatient and outpatient care. This was followed by cardio-vascular and genito-urinary cases for inpatient treatment and blood diseases in outpatient treatment. Interestingly, infections account for about a quarter of the ailments for both outpatient and inpatient care.
- At 10 per cent threshold, about 23 per cent of all households face catastrophic payments for healthcare. If one considers only those households that accessed some form of health care, about 58 per cent made catastrophic payments. The second measure is relevant keeping in view that at any point of time, only a fraction of the population falls sick and accesses healthcare.
- Catastrophic payments for outpatient care was significantly higher than inpatient care. The share of households facing catastrophic expenditure as well as its intensity is marginally higher in rural households (particularly those in the poorest quintile) than urban households.
- On average, about 8-9 per cent of households in the population were pushed below the poverty line due to healthcare payments. If one considers only affected households, the levels of impoverishment were about 17-20 per cent

## **Acknowledgements**

We would like to express our gratitude to the World Health Organization (WHO) for technical support for this study. We are indebted to Dr. Chandrakant Lahariya, National Professional officer, WHO Country Office for India, who contributed at all stages of this work including conceptualisation, data analysis, providing inputs on early drafts and the finalization of report. We are also thankful to Dr Hilde de Graeve, Ms. Hui Wang and Mr Fahdi Dkhimi of WHO for providing sparing valuable time for insightful discussions on early draft of this report and for sharing their detailed inputs. The report would not have been in its present form without the technical & financial support of WHO India, which is immensely appreciated.

## **Analyzing Household Expenditure on Health from the 71<sup>st</sup> Round of Survey by the National Sample Survey Organization in India**

Out-of-pocket expenses (OOPE) on health in India has been among the highest in the developing world (Doorsaler *et. al.* 2006, Doorsaler *et.al.* 2007). Several studies have highlighted the catastrophic implications of OOPE on health in the country, and its effect on impoverishment levels. Much of these are based on survey data collected nearly a decade ago and recent estimates of these are limited. Most of these have also been focused on National level aggregates or are confined to specific states (Karan *et.al.* 2016, Raban *et. al* 2013). This study intends to put together a detailed understanding of OOPE from the most recent (71<sup>st</sup> round) country-wide survey on households' expenditure on health care conducted by the National Sample Survey Organization (NSSO) across various Indian States in 2014. While most studies use surveys on consumption expenditures to estimate the catastrophic implications of OOPE and its impoverishment effect, we attempt to use the survey on health expenditure by households as it is relatively recent, and provides more disaggregated detailed information on household spending on health in the country. The analysis intends to provide a baseline understanding of the nature, extent and effect of OOPE on health in India, and could be used as a benchmark to track India's march towards Universal Health Coverage (UHC) in the near future.

The study has two parts. The first part documents the levels of OOPE across various Indian States and their association with access to public and private sources of care, levels of household consumption expenditure and insurance coverage, if any. This is shown separately for outpatient care, inpatient care (excluding childbirth) and childbirth. We also highlight issues related to the contribution of different components of spending in each of the three categories. In the second part, we first undertake a comparative analysis of the levels of OOPE on health calculated from the 68<sup>th</sup> round (the latest survey on consumption expenditure by households conducted in 2011-12) and the 71<sup>st</sup> round (the latest survey undertaken to estimate health expenses by households in 2014). We then highlight the levels of catastrophic spending and its effect on impoverishment based on the 2014 survey.

## Methodological Issues

Hospitalization expenses are estimated at the household level. For each case of hospitalization, expenses are reported in two parts: medical expenses and non-medical expenses.<sup>4</sup> Government sponsored health insurance schemes (GSHIS) primarily cover medical expenses, and to that extent an analysis of medical expenses on hospitalization assume particular relevance. However, an examination of NSSO data suggests that a significant number of households, particularly in the poorest quintile, have not reported medical and non-medical expenditures separately, but have reported total expenditure (Table 1). In the poorest quintile of Rajasthan, nearly a quarter of the households accessing inpatient care did not report medical expenses, although they reported total expenses (Table 1). Similarly, for childbirth and outpatient cases, 44 per cent and 14 per cent of the households in the poorest quintile of Rajasthan, did not report medical expenses, although they reported total expenses (Table 1). Using medical expenses therefore, may lead to exclusion of a substantial number of poor households, which in turn may induce a bias in the estimates. Also, in households where both medical and non-medical expenses were reported, on average, about 90 percent of total OOPE on hospitalization was in the nature of medical expenses, which implies that total expenses will strongly correspond to medical expenses (Table 2). We therefore use total expenses in all calculations of this analysis, unless mentioned otherwise.

We analyze expenditures separately for inpatient cases (excluding childbirth), outpatient cases and childbirth as inpatient cases (hereafter, referred to as inpatient, outpatient and childbirth). For each of these, we provide estimates of major States, along with the averages of different categories of States grouped under the National Health Mission (NHM), which includes the groups – (a) high-focus non-NE States, (b) non-high focus large States, (c) high-focus NE States and (d) non-high focus small States and UTs. For many of the small States and UTs, the number of households surveyed or the number of households with at least one inpatient, outpatient or childbirth case were small (Table 3). We therefore, do not report the figures for UTs (other than Delhi) and north-eastern States (other than Assam). Even for States like Goa, Himachal Pradesh

---

<sup>4</sup> Medical expenses include doctor's/surgeon's fee, medicines, diagnostic tests, bed charges and other medical expenses (blood, oxygen, etc.). Non-medical expenses include transport charges related to the treatment, food and lodging charges of the escort(s) and other non-medical charges.

and Uttarakhand the sample sizes of surveyed households are relatively small and the reported figures need to be interpreted with caution.<sup>5</sup> Further, in States like Delhi and Himachal Pradesh, separate estimates for rural and urban may be problematic as Delhi is largely urban, while Himachal Pradesh is predominantly rural. Figures for such States, need to be interpreted keeping in view the sample size of urban and rural areas. Further, while separating out expenditures of households by type of care (public or private sources) households which used different type of care for multiple episodes of hospitalization or outpatient visit (i.e. accessed public sources for some episode and private for others) were dropped. Such households (using mixed sources of care) constituted less than 5 per cent of all households. Similarly, while estimating average hospitalization expenses of households covered by government sponsored health insurance schemes, households which had individual members covered with different types of financial protection were dropped. Such households (with mixed coverage of insurance) constituted less than 1 per cent of households.

Information for inpatient and outpatient care expenditure were collected for different recall periods, and therefore, had to be converted to a uniform recall period. The recall period for inpatient care was 365 days and for outpatient care 15 days. To ensure comparability, all expenditures, including consumption expenditure of households were converted into annual figures for the analysis. The level of annual average per capita consumption expenditure (AAPCE) of households has been used as a proxy for income levels of households and their ability to pay.

Average expenditure across households were calculated in two ways. First, the averages are calculated across all households irrespective of whether or not any member of the household accessed health services for inpatient care, outpatient care or childbirth. Notably, on average, only about 13 per cent of all households were affected by an inpatient episode, 29 per cent of all households made at least one outpatient visit, and only 6 per cent of all households had an inpatient episode for childbirth (Table 4). It is expected that at any point of time, only a subset of population will require health care, and an average across all households may not reflect the average cost of households accessing such care. We therefore, calculate a second average across

---

<sup>5</sup> As per the report of NSSO on key indicators of the 71<sup>st</sup> round of survey conducted in 2014, the estimates of small states and UTs may not be reliable and needs to be interpreted with caution (NSSO 2015)

only those households, which had at least one episode in the respective category: hospitalization, outpatient visit or childbirth. We refer to these category of households as ‘affected households’ hereafter. It may be noted that about 8 per cent of all households had both inpatient episode and outpatient visits, about 10 per cent had only hospitalization episodes, and 25 per cent only outpatient visits. The remaining 57 per cent of households were unaffected.

A component-wise break-up of hospitalization expenses was not found to be very meaningful given the way the information is recorded by field investigators of the survey and the reported data. The ‘package component’ of hospitalization expense primarily relates to a fixed cost of some treatment package in a hospital. Sometimes, in addition to the package cost, the individual bears additional cost which is then recorded under items like diagnostic tests, bed charges, etc. In such cases, the amount reported under individual items is only partial in nature and do not include the complete expenditure on that item. Further, although all attempts are made to collect disaggregated information on individual items of expenditure, there are cases where individuals can provide only the total cost of hospitalization and not the break-up of spending on individual items. In such cases also, the total hospitalization expense is recorded under the item ‘package component’. Thus, while the amount recorded under ‘package component’ is heterogeneous in nature, the amount recorded under each of the other components of expenditure is incomplete. This tends to make a component-wise break-up of hospitalization expense misleading. Reported data also suggests that at the all India-level, only about half the hospitalized households reported expenditure on doctor’s fee (Table 5). The underreporting is not driven by households accessing public hospitals alone (Table 6). Even among households accessing private hospitals, about a quarter did not report doctor’s/surgeon’s fee. The reporting is similar in outpatient cases (Table 7, Table 8). We therefore, refrain from a component-wise analysis.

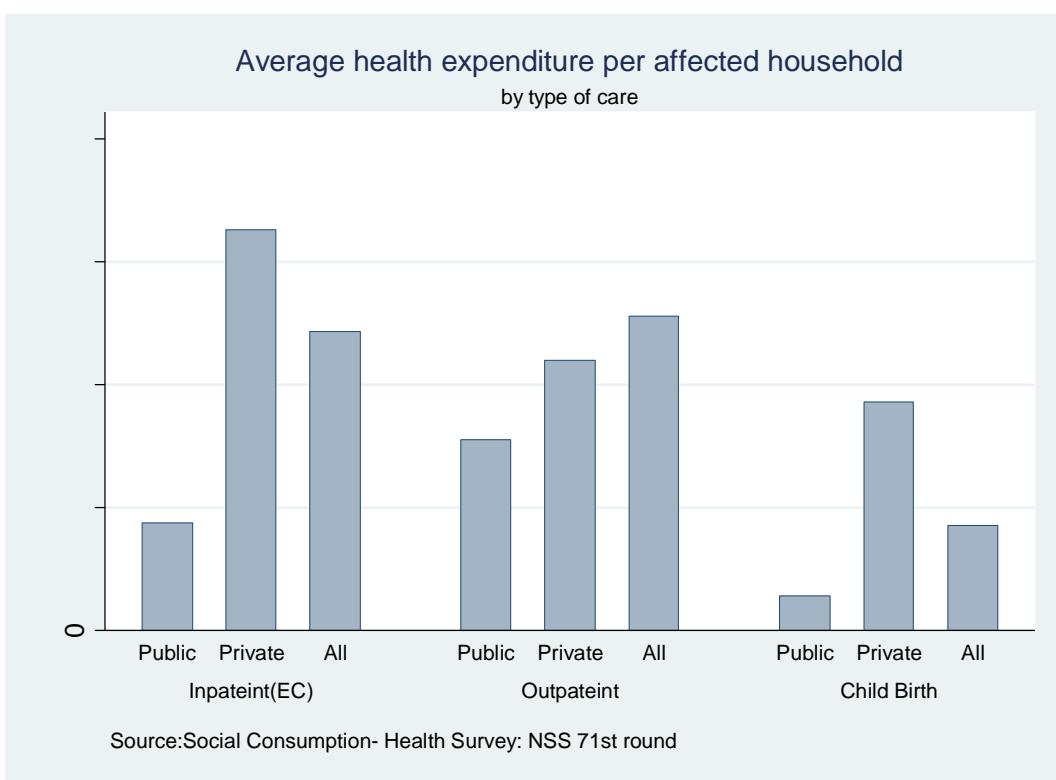

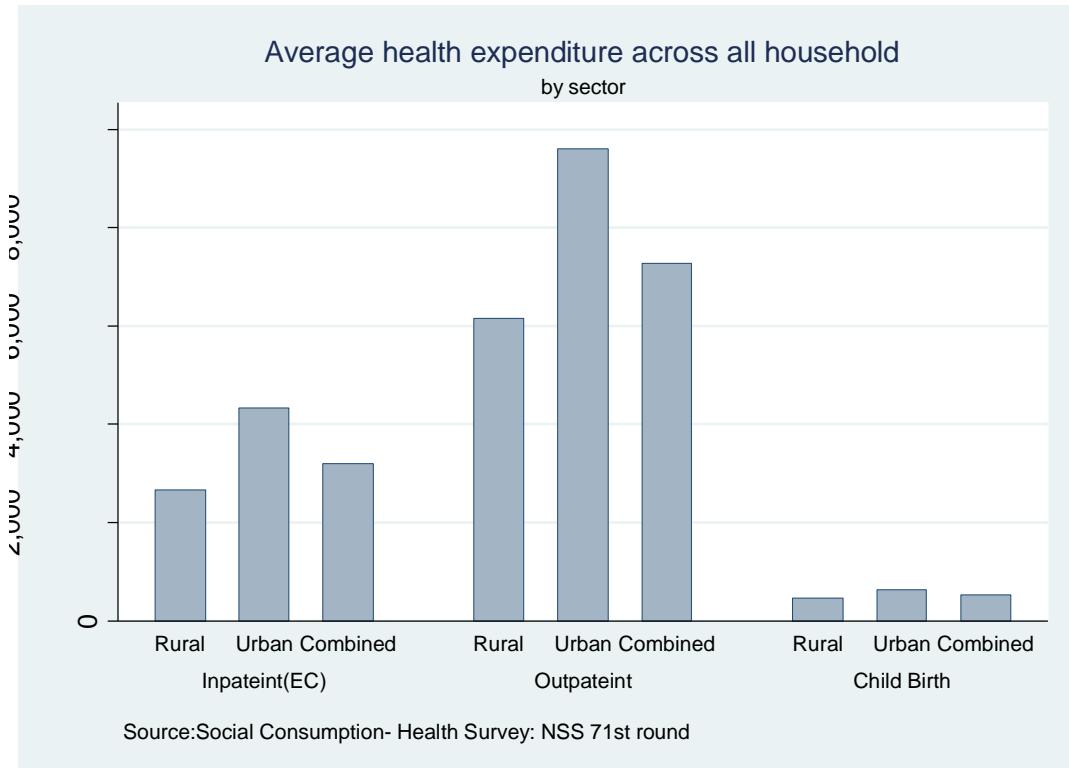

Total expenses have been adjusted for reimbursements in all cases. Notably, in India, the aggregate reimbursements are small due to low insurance penetration. In inpatient affected households, on average, only 6 per cent of total health expenditure was reimbursed. The corresponding figure for outpatient affected households was negligible: around 1 per cent (Table 9). Also, reimbursement was higher in urban than rural areas. In terms of number of cases reimbursed, only about 3 per cent of inpatient affected households and 0.2 per cent of outpatient affected households received reimbursements (Table 9).

## **1. Household Expenditures for Inpatient Care, Outpatient Care and Childbirth**

### **I. Average expenditure across households:**

*All households:* Annual average expenditure per household was significantly higher for outpatient care than inpatient care. For outpatient care, a household spent about Rs. 7276 per year, while for inpatient care, the corresponding figure was only about Rs. 3204 (Table 10, Table 25). For childbirth, the expenses were relatively small: about Rs. 523 per household (Table 33). In all cases, as expected, expenses in rural households were significantly lower than urban households (Table 10, Table 25 and Table 33).

*Affected households:* The annual average expenditure across affected households were however, roughly similar for inpatient and outpatient care. The average expenditure of households with at least one inpatient episode, was about Rs. 24,316, while in households which made at least one outpatient visit, the expenditure was about Rs. 25,550 (Table 10, Table 25). For childbirth, the expenditure was relatively small: Rs. 8511 per household per annum (Table 33). It is important to note that although the average expenditure across all households is substantially higher for outpatient care than inpatient care, the average across affected households is around the same range for the two. This is driven by the fact that the frequency of outpatient visits is much higher than inpatient episodes.

## II. Insurance coverage and average health expenditure

At the all-India level, only about a fifth of the inpatient affected households had some health insurance coverage (Table 11).<sup>6</sup> More than 80 per cent of this coverage was extended through government supported schemes (referred to as ‘GFHIS’ hereafter) (Table 10).<sup>7</sup> GFHIS schemes lowered expenditure in inpatient affected households. This is indicated by the fact that average expenditure was lower for households covered by GFHIS than those, which did not have any coverage (Table 12).<sup>8</sup> However, the lowering of expenditure through GFHIS was more among households belonging to richer quintiles than poorer quintiles (Table 13, Table 19, Table 20 and Table 21). Similarly, the lowering was more in urban areas than in rural areas. This is possibly because most of the government employees covered under CGHS and ESIS are located in urban areas and belong to relatively richer quintiles. On the other hand, households covered by GFHIS in rural areas and among the poorer quintiles, are supported by cashless insurance schemes of the government and their ability to incur inpatient expenditure in the absence of insurance support is relatively limited.

There are indications that the financial support extended by the government to poorer sections of the population through insurance schemes is inadequate. This can be derived from the fact that the rate of hospitalization is significantly lower in poorer quintiles than richer quintiles, despite the existing government support through insurance schemes (Table 24). The financial constraints are also reflected in the fact that more than half the inpatient affected households in the two poorest quintiles use public sources of care as they possibly cannot afford private sources (Table 23). The use of private sources and expenditure incurred increases as one moves from the poorest to the richest quintile of households and is therefore, linked to a household’s ability to pay.

**III. Variation of health expenditure by States and ability to pay:** The average expenditure by households on inpatient care, outpatient care and childbirth had a significant positive association with the average income levels of households in States (Table 10, Table 25, Table 33). In other words, expenditure on health care was relatively high among the richer States of the

<sup>6</sup> At least one member covered by insurance.

<sup>7</sup> These include schemes for government employees like CGHS and ESIS and other schemes to support the poorer sections of the population like RSBY and Aarogyasri.

<sup>8</sup> Notably, in a number of States, the sample size in terms of number of inpatient affected households covered by GFHIS is small, and therefore, the values need to be read with caution.

country. The correlation coefficients between the average expenditure of households on inpatient care and AAPCE was about 0.84. The corresponding figures for outpatient care and childbirth was 0.66 and 0.82 respectively.<sup>9</sup> The strong positive correlation coefficients indicate that the levels of health expenditure across States were strongly linked to households' ability to pay in those States. The strength of the association was stronger for inpatient care and childbirth than for outpatient care. This possibly arises from the fact that the average expense for inpatient care in a private facility is about 3-4 times higher than a public facility (Table 17). For outpatient, the difference between the cost of care in private *vis-a-vis* public is relatively small, and this is reflected in the fact that a larger share of people accesses private sources for outpatient treatment (Table 26, Table 27). In general, about 62 per cent of inpatient affected households and 75 per cent of outpatient affected households accessed private sources (Table 16, Table 26).

Interestingly, unlike inpatient and outpatient services, public sources provided much of the care for childbirth (Table 34). This is particularly driven by the dominant role of public sources in rural areas (Table 34). In urban areas however, much of the care for childbirth was provided through private sources. For childbirth, the expense in private facilities is about 6-7 times higher than the expense in public facilities (Table 35).

**IV. Variation of health expenditure by type of ailment:** Expenditure per episode was highest for the treatment of cancer for both inpatient and outpatient care (Table 18 and Table 28). This was followed by cardio-vascular and genito-urinary cases for inpatient treatment and blood diseases in outpatient treatment (Table 18, Table 28). Interestingly, infections account for about a quarter of the ailments for both outpatient and inpatient care (Table 18, Table 28).

## **2. Catastrophic Spending and its Impact on Impoverishment**

Out of pocket spending on health by households is considered 'catastrophic' when it exceeds a certain share of a household's consumption expenditure or capacity to pay. It is based on the rationale that when a household's OOPE on health shoots over a certain level, it faces financial hardships, which in turn may lead to impoverishment of the household. Although there is no

---

<sup>9</sup> The correlation coefficients were calculated using the average across all households and not affected households alone. Also, 16 major States were used to calculate the correlation coefficients.

consensus on the level of health payments beyond which it becomes catastrophic, many studies have considered thresholds between 10 to 25 per cent of household consumption expenditure as the benchmark. Some others have argued that thresholds of health payments should not be measured relative to a household's consumption expenditure, but should be linked to a household's 'capacity to pay'. Capacity to pay is defined as the expenditure that a household incurs after meeting its subsistence needs. Most often, food expenditure has been considered as expenditure for subsistence, and health payments that exceed a pre-defined share of non-food expenditure (usually 40 per cent) has been termed as catastrophic. As poor households have a relatively high share of expenditure on food, their ability to make health care payments is relatively low, and this aspect is captured in the latter approach. More recent studies have also tried to incorporate the effects of dissaving, borrowing and sale of assets for meeting health expenses into the measurement of catastrophic spending.

In the Indian context, studies have used two different types of surveys to measure catastrophic spending: NSS surveys on household consumption expenditures, and surveys that are carried out to estimate household expenditures on health. Each of these surveys have advantages/disadvantages of their own for estimating catastrophic health expenditures. The consumer expenditure survey allows one to break-up spending on food and non-food items, and estimate catastrophic spending as a proportion of non-food expenditure. The survey on health expenditures does not facilitate this. In contrast, the survey on health expenditures provides information on sources of finance for spending on health care (like borrowings, sale of assets, etc.), which allows one to derive insights into the effects of dissaving, borrowing, sale of assets in catastrophic spending.

In an earlier study, Raban *et.al.* 2013 had shown that the estimated mean OOPE on health and the corresponding share of households facing catastrophic health expenses were higher in the health survey than in the survey on consumption expenditures conducted by NSS. The estimates were compared using information on NSS consumer expenditure surveys conducted in 2004-05 and 2009-10 with the NSS health survey conducted in 2004. To understand the implications of using the health survey *vis-à-vis* the consumer expenditure in more recent surveys, we compare, broad estimates of OOPE on health from the 71st round (2014) and the 68<sup>th</sup> round (2011-12) before working out the estimates of catastrophic spending and its impact of impoverishment.

This provides an idea of how estimates of catastrophic spending and impoverishment derived from the 71<sup>st</sup> round of health survey should be viewed *vis-à-vis* estimates derived from consumer expenditure survey 2011-12.

A comparison of average monthly per capita consumption expenditure (MPCE) from the two surveys (at the All-India) level suggests that the reported levels of consumption expenditures are higher when estimated from the 68<sup>th</sup> (consumer expenditure) round than the 71<sup>st</sup> (health) round (Table 40). In contrast, the reported health expenditures are lower in the consumer expenditure round (68<sup>th</sup>) than the health round (71<sup>st</sup>) (Table 40). This results in a situation where catastrophic spending estimated from the health survey is markedly higher than the estimates derived from the consumer expenditure survey (Table 40). It is important to note that the proportion of households accessing outpatient care are significantly different across the two surveys: 33 per cent in 71<sup>st</sup> (health) round as opposed to 78 per cent in the 68<sup>th</sup> (consumer expenditure) round (Table 41). In contrast, for inpatient care, the shares are only marginally different: 18 *vs.* 14 per cent (Table 41). Part of the difference could arise from the fact that the recall period for outpatient care is different in the two surveys: 30 days in the 68<sup>th</sup> round and 15 days in the 71<sup>st</sup> round. This is unlike inpatient care, where the recall period in both the surveys is 365 days.

## **2.1Measures of Catastrophic Health Expenditure (CHE)**

### *(a)Headcount of households facing catastrophic health expenditure*

We first estimate the proportion of households that face catastrophic spending in the population. This dimension broadly corresponds to the *Catastrophic payment headcount* ( $H_{cat}$ ) defined by Wagstaff and Doorslaer (2003) which has been widely used by various scholars to measure CHE. It indicates the fraction of households whose health expenditure as a proportion of total household consumption expenditure exceeds a threshold  $Z_{cat}$ . Algebraically, if  $X_i$  = Total consumption expenditure of the  $i^{th}$  household,  $T_i$  = Total health expenditure of the  $i^{th}$  household,  $Z_i = T_i/X_i$ , and  $Z_{cat}$  = pre-defined threshold, then, the  $i^{th}$  household is considered to be facing catastrophic health expenditure if  $Z_i > Z_{cat}$ . Further, if  $O_i$  is the extent of catastrophic overshoot, i.e.  $O_i = Z_i - Z_{cat}$  and  $E_i = 1$  if  $O_i > 0$ , and  $E_i = 0$  otherwise, then

$$H_{cat} = 1/N \sum_{i=1}^n E_i ----- (i)$$

where N is the total number of households

We measure  $H_{cat}$  in two ways. First, we estimate the share of households facing catastrophic health expenditure among all households. Second, we estimate the share households facing catastrophic health expenditure among only those households that incurred some health expenditure. The first measure is widely used, and provides an idea on the share of households in the entire population that face CHE (irrespective of whether or not they fell sick). However, at any point of time, only a certain fraction of the population falls sick (or accesses health care) and incurs health expenditure. We therefore, use a second measure that takes into account this aspect, and examines the headcount of households facing CHE only among those households which had to access at least some outpatient care, inpatient care or both. As earlier, we call these affected households. In other words, the second measure answers the question: of the households that accessed healthcare, what proportion of households faced catastrophic health payments. Algebraically, in equation (i) the difference between the first and the second measure lies in what constitutes N. In the first measure, N is taken as all households (irrespective of whether or not they accessed health care), while in the second measure N is taken as only those households which had accessed some healthcare.

*(b) Intensity of catastrophic health expenditure*

The headcount ratio ( $H_{cat}$ ) ignores the magnitude (or the intensity) of the overshoot  $O_i$  in households facing catastrophic spending. To take this into account, Wagstaff and Doorslaer (2003) suggested the measurement of *mean positive overshoot*, which is defined as the average amount by which the  $Z_i$  exceeds  $Z_{cat}$  only in households which face catastrophic expenditure. Thus,

$$MPG_{cat} = \frac{\sum_{i=1}^n O_i}{\sum_{i=1}^n E_i}$$

*(c) Distribution of catastrophic health expenditure by income classes*

To understand how catastrophic health payments are distributed by income/expenditure classes, we use concentration indices for headcount dummy  $E_i$  and the overshoot variable  $O_i$ , which are denoted by  $C_E$  and  $C_O$  respectively.  $C_E$  and  $C_O$  are based on relative ranking of households by income distribution and their exposure to CHE. A positive value of the index indicates that catastrophic payments are relatively more in richer households, while a negative value points towards a relatively high concentration of catastrophic payments among the poor.

## **2.2 Estimates of Headcount and Intensity of Catastrophic Payments**

In 2014, at the all-India level, about 22.9 per cent of households faced catastrophic payments at 10 per cent threshold (Table 42). Raban *et. al.* (2013) estimated similar figures from the 2004 round of health survey. A comparison of the figures reported by Raban *et. al.* 2013 for 2004 and the estimates here for 2014 suggests that the share of households making catastrophic payments has increased between 2004 and 2014. Table 44 provides state-wise headcount of households making catastrophic payments at 10 per cent threshold.

If one considered only households that accessed some healthcare (affected households), more than half the households (57.9 per cent) had to make catastrophic payments, at 10 per threshold (Table 42). Even if one uses a 20 per cent threshold, for around a third (38 per cent) of the households accessing health care, healthcare payments were catastrophic in nature.

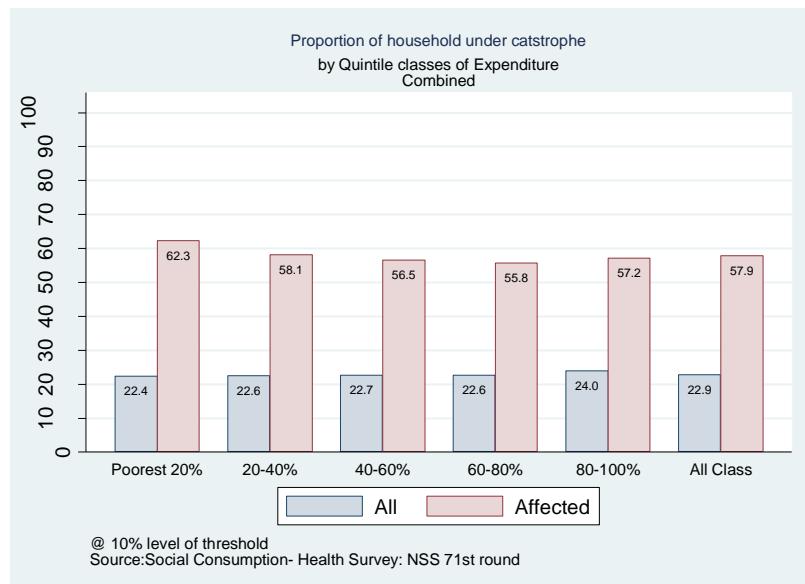

The intensity of catastrophic payments was also very significant. On average, health care payments were 39 per cent above the threshold (at 10 per cent threshold) (Table 42). If one uses a threshold of 25 per cent, the average catastrophic payments are about 50 per cent more than the threshold (Table 42).

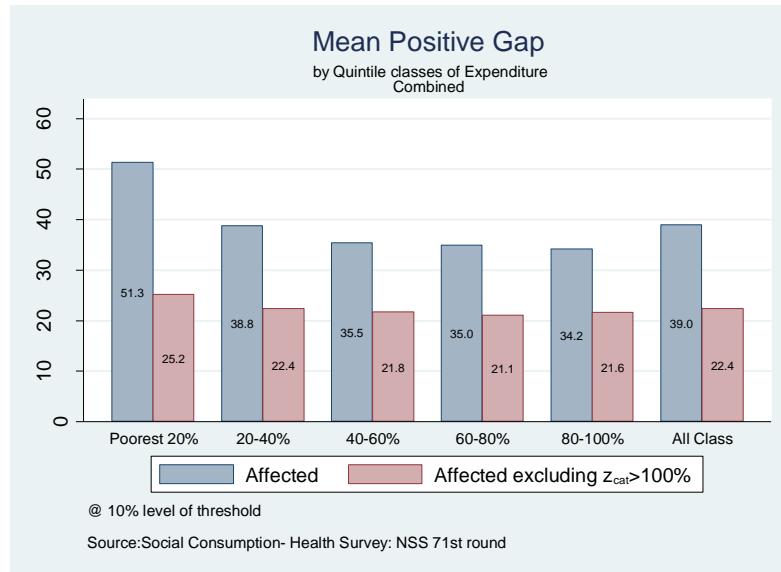

It is noteworthy that in about 2 per cent of all households (5 per cent of affected households), healthcare payments were more than the total consumption expenditure. These households had a significant effect on the estimates, in particular  $MPG_{cat}$  (as  $O_i$  in such households is large). It is notable that the intensity of catastrophic payments ( $MPG_{cat}$ ) reduces sharply if one excludes these households (Comparing Table 42 and Table 43). Understandably, the difference increases

if one moves from lower to higher thresholds. At 20 and 25 per cent threshold, the intensity of catastrophic payments reduce by half if one excludes these households (Table 42, Table 43).

The headcount and intensity of catastrophic payments appear to be relatively high among the poorer households of the population (Table 45). This is reflected in the fact that the concentration indices  $C_E$  and  $C_O$  are largely negative among affected households (Table 45). Notably,  $C_E$  and  $C_O$  for all households may be misleading when one uses all households, as it also includes a large number of households, which do not incur health expenditure.

In general, catastrophic payments for outpatient care is significantly higher than inpatient care (Table 42, Table 43). Also, the share of households facing catastrophic expenditure, as well as its intensity is marginally higher in rural households than urban households (Table 42 , Table 43). An examination of State-wise measures also suggests that for most States, the concentration index is negative suggesting that the burden of catastrophic payments is relatively high among the poor (Table 47).

## 2.3 Impoverishment Effect of Health Payments

Healthcare payments may also drive households below the poverty line. We estimate the proportion of population below the poverty line before and after healthcare payments to derive insights on the impoverishing effects of health expenses. As in Wagstaff and Doorslaer (2003), we assume  $Z_{pov}$  is the poverty line and proceed as follows:

We first derive an estimate if the proportion of population below the poverty line before healthcare payments. This is given by

$$H_{pov}^{pre} = \frac{1}{N} \sum_{i=1}^N P_i^{pre}$$

where  $P_i^{pre} = 1$ , if  $X_i$  (consumption expenditure of the  $i^{\text{th}}$  household) is less than  $Z_{pov}$ , otherwise zero.

We then estimate the proportion of population below the poverty line after healthcare payments. This is given by

$$H_{pov}^{post} = \frac{1}{N} \sum_{i=1}^N P_i^{post}$$

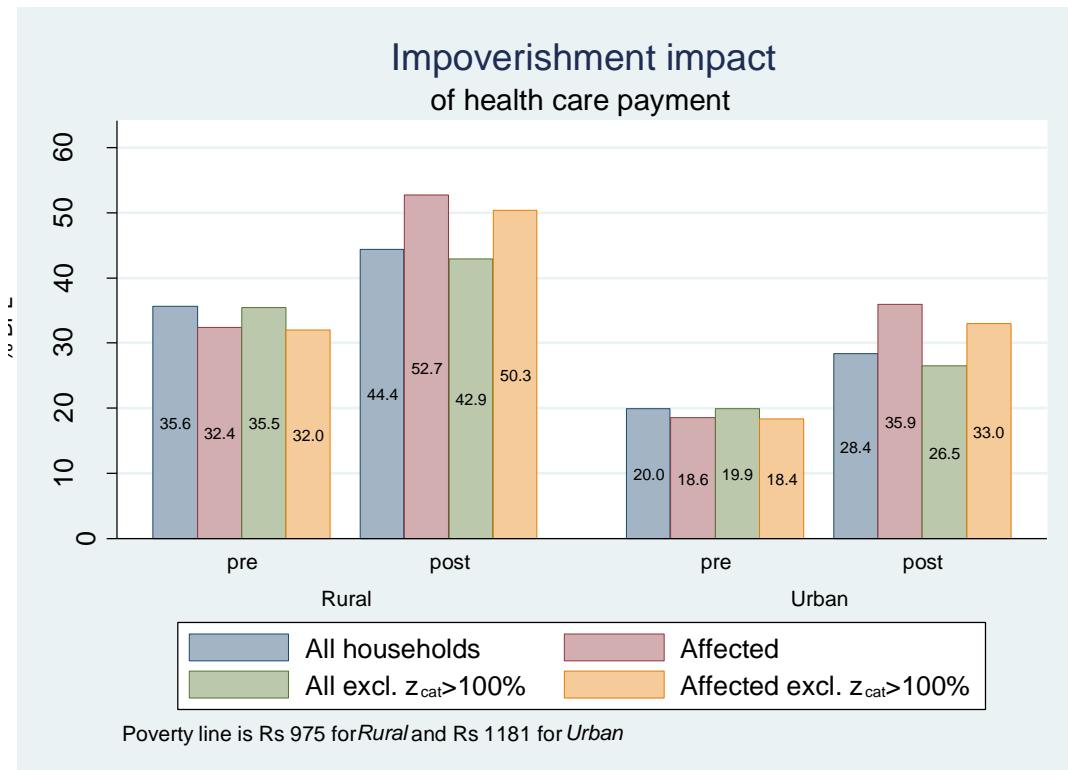

where  $P_i^{post} = 1$ , if  $X_i - T_i$  (healthcare expenditure of the  $i^{\text{th}}$  household) is less than  $Z_{pov}$ , otherwise zero.

The impoverishing effect is then calculated as:

$$PI^H = H_{pov}^{post} - H_{pov}^{pre}$$

We use rural and urban poverty lines for India in 2011-12, estimated by Tendulkar Committee. It is derived from the consumption expenditure derived from the mixed recall period and is about Rs. 816 and RS. 1000 per capita per month for rural and urban areas. The poverty lines have been updated to 2014 prices using the Consumer prices indices for the country as a whole as well as States.

On average, about 8-9 per cent of households in the population were pushed below the poverty line due to healthcare payments (Table 46). If one considers only affected households, the levels of impoverishment are about 17-20 per cent (Table 46). State-wise variation of impoverishment levels using State-specific poverty lines are shown in Table 48. If one uses the international poverty line of \$1.9 per day, and adjusts it for purchasing power parity, the corresponding monthly per capita consumption expenditure turns out about Rs. 978. The proportion of population below the poverty line pre-and post-healthcare payments are shown in Table 46

## **Appendix Tables**

Table 1. Sample Number of cases where medical expenses have not been reported as share of cases that reported total expenses (in episodes of inpatient care and childbirth and per person in outpatient cases) (Rural + Urban)  
(per cent)

States	Inpatient cases		Childbirth cases		Outpatient cases	
	Poorest 20 %	All	Poorest 20 %	All	Poorest 20 %	All
<b>High-focus non-NE states</b>	8	5	16	13	5	3
Jammu & Kashmir	0	0	3	4	0	0
Himachal Pradesh	2	2	14	11	1	2
Uttaranchal	8	3	5	2	0	2
Rajasthan	24	13	44	29	14	11
Uttar Pradesh	3	3	13	9	2	2
Bihar	5	4	6	5	3	1
